#### Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see www.iso.org/directives).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the deviction and/or on the ISO list of patent declarations regarrities www.iso.org/patents).

Any trade name used in this document is **lofor**mation given for the convenience of users and does not constitute an endorsement.

For an explanation on the meaning of ISO, specific terms and expressions related to conformity assessment, as well as information about 1905 adhere text to the WTO principles in the Technical Barriers to Trade (TRT) see the following URIF 1544 WMM 21 Supplies ideal by information

to Trade (TBT) see the following URL: Foreward: Supplication tary information

The committee responsible for the document is ISO/TC 164. Mechanical testing of metals, Subcommittee SC 3. Hardness testing.

This third edition cancels and captaces the second edition (ISO 6508-1:2005), which has been technically revised.

ISO 6508 consists of the following parts, under the general title Metallic materials - Rockwell hardness test:

- Part 1: Test method
- Part 2: Verification and calibration of testing machines and indexters
- Part 3: Calibration of reference blocks

## Metallic materials — Rockwell hardness test —

## Part 1:

## Test method

#### 1 Scope

This part of ISO 6508 specifies the method for Rockwell regular and Rockwell superficial hardness tests (scales and applicable range of application according to Table 1) for metallic materials and is applicable to stationary and portable hardness testing machines.

For specific materials and/or proficts, other specific International Standards apply (for instance, ISO 3738-1 and ISO 4498).

NOTE Attention is drawn to the 134 (134) leave of tungsten carbide composite for ball indenters is considered to be the standard type of Rock 1440 indentate ball. Steel indenter balls are allowed to continue to be used only when complying with Annex A:

#### 2 Normative references

The following documents: in which is in part; are not attively referenced in this document and are indispensable for its applies. For undated references, the left applies. For undated references, the latest applies. For undated references, the latest applies.

ISO 6508-2:2015, Métalki materials — Rockwell hardness test — Part 2: Verification and calibration of testing machines:

ISO 6508-3:2015, Metallic materials — Rockwell hardness test — Part 3: Calibration of reference blocks

## 3 Principle

An indenter of specified size, \$\$\frac{\text{Mathe}}{\text{int}}\$ \text{Ainthinterial} is forced into the surface of a test specimen under two force levels using the specifice-original force is applied and the initial indentation depth; is pleasured, followed by the application and removal of a specified additional force, returning to the Peliminary force. The final indentation depth is then measured and the Rockwell hardness value is derived from the difference, h, in the final and initial indentation depths and the two constants \$M\$ and \$S\$ (see Figure 1. Table 1 and Table 21 as:

Rockwell hardness = 
$$N - \frac{h}{s}$$
 (1)

#### 4 Symbols, abbreviated terms and designations

4.1 See Table 1, Table 2, Table 3, and Figure 1.

Table 1 - Rockwell Regular scales

Rockwell Regular hardness cale	Hardness symbol Unit	Type of indenter	Preliminary force	Total force	Scaling Constant	Full Range Constant	Applicable range of applica- tion (Rockwell Regular
cale			F <sub>0</sub>	F	S	N	hardness scales)
A	HRA	Diamond cone	98,07 N	588,4 N	0,002 mm	100	20 to 95 HRA
В	HRBW	Ball 1,587 5 mm	98,07 N	980,7 N	0,002 mm	130	10 to 100 HRBW
С	HRC	Diamond cone	98,07 N	1,471 kN	0,002 mm	100	20a to 70 HRC
D	HRD	Diamond cone	98,07 N	980,7 N	0,002 mm	100	40 to 77 HRD
E	HREW	Ball 3,175 mm	98,07 N	980,7 N	0,002 mm	130	70 to 100 HREW
F	HRFW	Ball 1,587 5 mm	98,07 N	588,4 N	0,002 mm	130	60 to 100 HRFW
G	HRGW	Ball 1,587 5 mm	98,07 N	1,471 kN	0,002 mm	130	30 to 94 HRGW
Н	HRHW	Ball 3,175 mm	98,07 N	588,4 N	0,002 mm	130	80 to 100 HRHW
K	HRKW	Ball 3,175 mm	98,07 N	1,471 kN	0,002 mm	130	40 to 100 HRKW

The applicable range of application can be extended to 10 HRC if the surfaces of the diamond cone and spherical tip are polished for a penetration depth of at least 05 mm.

Table 2 - Rockwell Sinjerficial scales

Rockwell Superficial hardness scale	Hardness symbol Unit	Type of indenter	Prěliminary. Idred		Scaling Constant	Full Range Constant	Applicable range of appli- cation (Rock- well Superficial hardness scales)
15N	HR15N	Hiamond cone.	•	147,1 N	0,001 mm	100	70 to 94 HR15N
30N	• • • •	Diamond cone		294,2 N	0,001 mm	100	42 to 86 HR30N
45N	HR45N*	Diamend cone			0,001 mm	100	20 to 77 HR45N
15T	HR15TW	Ball 1,587 5 mm	29, <b>42 N</b>	147,1 N	0,001 mm	100:	67 to 93 HR15TW
30 <b>T</b>	HR30TW	Ball 1,587 5 mm	29.42 N	294,2 N	0,001 mm	100:	29 to 82 HR30 <b>T</b> W
45T	HR45TW	Ball 1,587 5 mm.	: 29,42 N	441,3 N	0,001 mm	:100	10 to 72 HR45TW

Scales using indenter balls with diameter 6350 mm and 12,70 mm may also be used, if specified in the product specification or by special agreement. See ASTM E 18 for additional scales using these ball sizes.

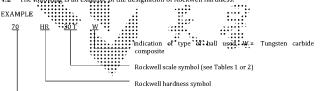

NOTE 1 For certain materials, the applicable range of application might be narrower than those indicated.

NOTE 2 The numbers representing the test forces were originally based on units of kgf. For example, the total test force of 30 kgf has been converted to  $294.2\,N$ .

Table 3 - Symbols and abbreviated terms

Rockwell hardness value

NOTE 1  $\,$  Previous versions of this part of ISO 6508 allowed the use of steel indenter balls, which required the suffix S.

NOTE 2 For the HR30TSm and HR15TSm scales defined in  $\underline{\Lambda}\underline{n}\underline{n}\underline{n}\underline{n}$ , a capital S and a lower-case m is used indicating the use of steel indenter balls and a diamond spot specimen holder.

- 5.1 Testing machine, shall be capelled applying the test forces for spine or all of the Rockwell hardness scales as shown in Table 1. perfable 2. performing the procedure defined in <u>Clause 7</u>, and complying with all of the requirements defined in ISO 6508-2:2015.
- 5.2 Spheroconical diamond indenter, shall be in accordance with ISO 6508-2:2015, with an included angle of 120° and radius of curvature at the tip of 0,2 mm. Diamond indenters shall be certified for use for either
- only the regular Rockwell diamond scales,
- only the superficial Rockwell diamond scales, or
- both the regular and the superficial Rockwell diamond scales.
- 5.3 Ball indenter, shall be tungsten carbide composite in accordance with ISO 6508-2:2015, with a diameter of 1,587 5 mm or 3,175 mm (see Note 1 and Note 2)
- NOTE 1 Ball indenters normally consist of a spherical ball and a separate appropriately designed holder. Singlepiece spherically tipped indenters are allowed, provided that the surface of the indenter that makes contact with the test piece meets the size, shape, finish, and hardness requirements defined in ISO 6508-2:2015, 6.3.1, and meets the performance requirements of ISO 6508-2:2015, 6.3.2.

NOTE 2 Attention is drawn to the fact that the use of tungsten carbide composite for ball indenters is the standard type of Rockwell indenter ball. Steel indenter balls can only be used when performing Rockwell HR3OTSm and HR15TSm tests according to Annex A.

#### 6 Test piece

- 6.1 The test shall be carried out on a surface which is smooth and even, free from oxide scale, foreign matter and, in particular, completely free from lubricants, unless specified otherwise in product or materials standards. An exception is made for reactive metals, such as titanium, which might adhere to the indenter. In such situations, a suitable lubricant such as kerosene may be used. The use of a lubricant shall be reported on the test report.
- 6.2 Preparation shall be carried out in such a way that any alteration of the surface hardness due to excessive heating or cold-working for example, is minimized. This shall be taken into account, particularly in the case of low-depth indentations.
- 6.3 The thickness of the test preceded in layer under test (minimum values are given in Aunce 19.) shall be at least 10 times the permanent indentation depth for diamond indenters and 15 times the permanent indentation depth the ball bulleters, unless it can be demonstrated that the use of a thinner test piece does not affect the pressure haddness value. In general, no deformation should be visible on the back of the test piece after the test, although not all such marking is indicative of a bad test.

See <u>Annex A</u> for special requirements; for testing very thin sheet metal using the HR30TSm and HR15TSm scales.

6.4 For tests on contact cylinaridal solutaces and spherical surfaces, see 7.11.

# 7 Procedure

- 7.1 This paragraph 6508 has been developed with a laboratory temperature requirement of 10°C to 35°C. For environments and side the skeed requirement, it is the responsibility of the testing laboratory to assess the impact or testing data produced with testing mechanics operated in such environments. When testing is performed outside the recompleted demperature limits of 10°C tr 35°C, the temperature shall be recorded and reported.
- NOTE If significant temperature gradients are present during testing and/or calibration, measurement uncertainty can increase and out of colorance conditions can occur.
- 7.2 The daily verification defined in <u>Annex E</u> shall be performed before the first test of each day for each scale to be used. The condition of diamond indenters should be checked according to <u>Annex F</u>.
- 7.3 After each change, or removal and replacement, of the indenter, indenter ball, or test piece support, perform at least two tests and discard the results, then determine that the indenter and the test piece support are correctly mounted in the machine by performing the daily verification process defined in <u>Annex E.</u>
- 7.4 The diamond or ball indenter shall have been the indenter used during the last indirect verification, if the indenter was not used during the indirect verification and is being used for the first time, it shall be verified in accordance with the daily verification given in <u>Annex E</u> using at least two test blocks (one from the low and high ranges as defined in ISO 6508-2:2015, Table 1) for each Rockwell scale that is normally used. This does not apply to replacing a ball.

The test piece shall be placed on a rigid support and supported in such a manner that the surface to be indented is in a plane normal to the axis of the indenter and the line of the indenting force, as well as to avoid a displacement of the test piece.

Products of cylindrical shape shall be suitably supported, for example, on centering V-block or double cylinders made of material with a Rockwell hardness of at least 60 HRC. Special attention shall be given to the correct seating, bearing, and alignment of the indenters, the test piece, the centering V-blocks, and the specimen holder of the testing machine, since any perpendicular misalignment might result in incorrect results

**7.6** Bring the indenter into contact with the test surface and apply the preliminary test force,  $F_0$ , without shock, vibration, oscillation, or overload. The preliminary force application time should not exceed 2 s. The duration of the preliminary test force,  $F_0$ , shall be  $3 + \frac{1}{2}$  s.

The requirements for the time durations are given with asymmetric limits. NOTE

EXAMPLE  $3 + \frac{1}{2}$  s indicates that 3 s is the ideal time duration, with an acceptable range of not less than 1 s (3 s - 2 s) to not more than 4 s (3 s + 1 s).

- Measure the initial indentation double. For the manual (dial-indicator) machines, this is done by setting the indicating dial to its set-point or zero position. For many automatic (digital) machines, the depth measurement is made automatically without the user's input and might not be displayed.
- 7.8 Apply the additional force  $F_1$  without shock y legation, oscillation, or overload to increase the force from  $F_0$  to the total force, F. For the regular lock web stage tests apply the additional test force,  $F_1$ , in not less than 1 s and not more than S s. For an interior than 1 s and not more than S so that S is a substitutional test force,  $F_1$ , in less than S so that S is a substitutional test force,  $F_1$ , in less than S so that S is a substitution of S is a substitution of S so that S is a subst during indirect verification:
- NOTE There is evidence that some waterials might be ensitive to the rate of straining which causes small changes in the value of the yield stress. The corresponding effect on the termination of the formation of an indentation can make an observation in the two less value.

  7.9 The total test force, F, shall be maintained for a duration of  $5^{+1}_{-3}$  s. Remove the additional test force,  $F_1$ , and, while the preliminary test force,  $F_2$ , is Maintained, after  $4^{+1}_{-3}$  s. The final reading shall be made.

As an exception for test materials exhibiting excessive plastic flow (indentation creep) during the application of the total test force, special considerations might be necessary since the indenter will continue to penetrate. When materials require the use of a total force duration that exceeds the 6 s allowed by the tolerances, the actual extended total force duration used shall be reported following the test results (for example, 65 HRF/10 s).

7.10 Measure the final indentation depth while the preliminary test force is applied. The Rockwell hardness number is calculated from the permanent indentation depth, h, using the formula given in Formula (1) and the information given in Table 1, Table 2, and Table 3. For most Rockwell hardness machines, the depth measurement is made in a manner that automatically calculates and displays the Rockwell hardness number.

The derivation of the Rockwell hardness number is illustrated in Figure 1.

7.11 For tests on convex cylindrical surfaces and spherical surfaces, the corrections given in Annex C (Table C.1, Table C.2, Table C.3 or Table C.4) and in Annex D (Table D.1) shall be applied. The correction values shall be reported on the test report.

In the absence of corrections for tests on concave surfaces, tests on such surfaces should be the subject of special agreement.

- 7.12 Throughout the test, the apparatus shall be protected from shock or vibration.
- 7.13 The distance between the centres of two adjacent indentations shall be at least three times the diameter of the indentation. The distance from the centre of any indentation to an edge of the test piece shall be at least two and a half times the diameter of the indentation.

#### 8 Uncertainty of the results

A complete evaluation of the uncertainty should be done according to ISO/IEC Guide 98-3.[3]

Independent of the type of sources, for hardness, there are two possibilities for the determination of the uncertainty.

- One possibility is based on the evaluation of all relevant sources appearing during a direct calibration.
   As a reference, an EURAMET Guide CG-16<sup>[4]</sup> is available.
- The other possibility is based on indirect calibration using a hardness reference block (abbreviated
  as CRM certified reference material) [2][3][4][5] A guideline for the determination is given in Annex G.

# 9 Test report

The laboratory shall record at least the following information and that information shall be included in the test report, unless agreed by the parties concerned:

- a) a reference to this part of ISO H308 (12:150.6508-1);::
- all details necessary for in compare itentification of the test piece, including the curvature of the test surface;
- c) the test temperature, if it is not within the limits of 10 °C to 35 °C;
- d) the hardness result in the format defined in 4.2:
- e) all operations 100 specified in this part of ISO 6508, or regarded as optional;
- f) details of any occurrence which might have affected the result;
- g) the actual extended total force duration time used, if greater than the 60 allowed by the tolerances;
- h) the date the test was performed
- i) if conversion to another hardness scale is also performed, the basis and method of this conversion shall be specified (see ISO 18265).

## 10 Conversions to other hardness scales or tensile strength values

There is no general process for accurately converting Rockwell hardness into other scales, or hardness into tensile strength. Such conversions, therefore, should be avoided, unless a reliable basis for conversion can be obtained by comparison tests (see also ISO 18265).

# Annex A (normative)

# Special HR30TSm and HR15TSm test for thin products

#### A.1 General

This test is applicable to thin sheet metal products having a maximum thickness of 0,6 mm to the minimum thickness indicated in the product standards, and of a maximum hardness of 82 HR30TSm or 93 HR15TSm. The product standard shall specify when the Special HR30TSm or HR15TSm hardness test is to be applied.

This test is carried out under conditions similar to those in the HR30TW or HR15TW test defined in this part of ISO 6508. The appearance of deformation condent between the test pieces below the indent is permitted.

NOTE 1 The Sm in the scale designations in that a steel ball indenter and a diamond spot specimen holder are used for this testing.

NOTE 2 Prior to testing, hardness tests should be made on thin sheet samples of a known hardness to verify that the specimen holder surface does not affect the measurement of the specimen holder surface does not affect the measurement of the specimen holder surface does not affect the measurement of the specimen holder.

The following requirements shall be met. ittadtlituot to those specified in this part of ISO 6508.

## A.2 Ball indenter

A hardened steel ball indepter, that means the requirements of ISO 6508-2:2015, with a diameter of 1,587 5 mm shall be used for this testing.

# A.3 Test piece support

The test piece support shall comprise spolished bod smooth flat diamond surface approximately 4.5 mm in diameter. This support surface shalf be provided in the exist of the indenter and shall be perpendicular to it. Care shall be taken true that it is seated correctly on the machine table.

## A.4 Test piece preparation

If it is necessary to remove material from the test piece, this should be done on both sides of the test piece. Care shall be taken to ensure that this process does not change the condition of the base metal, for example, by heating or work hardening. The base metal shall not be made thinner than the minimum allowable thickness.

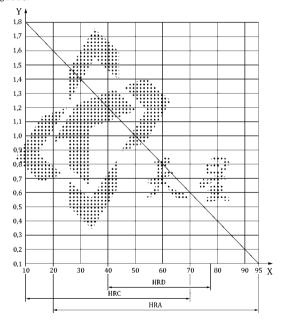

## A.5 Position of the test piece

The distance between the centres of two adjacent indentations or between the centre of one of the indentations and the edge of the test piece shall be at least 5 mm, unless otherwise specified.

# Annex B (normative)

# Minimum thickness of the test piece in relation to the Rockwell hardness

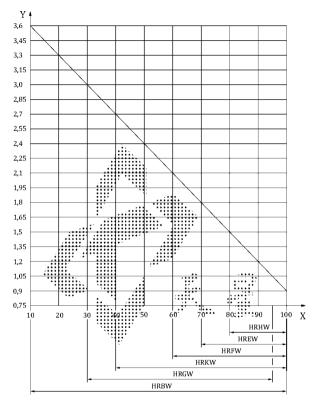

The minimum thickness of the test piece, or of the layer under test, is given in Figure B.1, Figure B.2, and Figure B.3.

#### Kev

# Annex C (normative)

# Corrections to be added to Rockwell hardness values obtained on convex cylindrical surfaces

For tests on convex cylindrical surfaces, the corrections given in Table C.1, Table C.2, Table C.3, or Table C.4 shall be applied. For radii other than those given in these tables, corrections may be derived by linear interpolation.

Table C.1 — Test with diamond cone indenter (scales A. C. and D)

Rockwell hard-			.:::	Radi	us of curva	ture

# Annex E

# **Daily Verification Procedure**

#### E.1 General

A daily verification of the machine shall be carried out on each day that the machine is used by performing tests in each hardness scale that is to be used that day. Select at least one hardness reference block hat meets the requirements of ISO 6508-3:2015 from the ranges defined in Table E.1. It is recombineded that the hardness level selected be close to the levels to be tested. Only the calibrated surface of the test blocks are to be used for testing. Perform at least two indentations on each block and calculate the bias and repeatability of the results using the forthulas defined below. If the bias and repeatability are within the permissible limits given in Table E.1, the problem have be regarded as satisfactory. If not, verify that the indenter, specimen holder, and tester 136 11 310d condition and repeat the test. If the machine continues to fail the daily test, an indirect verification and repeating to 150 5508-2:2015. Clause 5, shall be performed.

A record of the daily verification results should be maintained over a period of time, and used to measure reproducibility and monitor drift of the machine.

# E.2 Bias

The bias, b, of the testing machine in Rockwell units moder the particular verification conditions, is expressed by Formula [E1]:

$$b = \overline{H} - H_{CRM} \ . \tag{E.1}$$
 where 
$$\overline{\pi} \quad \text{is the mean hardness value from $2d$rmula (E.2)}.$$

Hanne is the certified hardness of the reference block used.

The mean hardness value of the indentations  $\overline{H}$  is defined according to Formula (E.2):

$$\overline{H} = \frac{H_1 + \dots + H_n}{n} \tag{E.2}$$

where

 $H_1, H_2, H_3, H_{4,...,}H_n$  are the hardness values corresponding to all the indentations arranged in increasing order of magnitude;

n is the total number of indentations.

## E.3 Repeatability range

To determine the repeatability range for each reference block, let  $H_1,...,H_n$  be the values of the measured hardness arranged in increasing order of magnitude.

16 © ISO 2015 - All rights reserved

17

The repeatability, r, of the testing machine in Rockwell units, under the particular verification conditions, is determined by Formula (E.3):

$$r = H_n - H_1 \tag{E.3}$$

Table E.1 — Permissible repeatability range and error of the testing machine

#### EXAMPLE

A low-hardness HRC block gave the following daily verification results:

#### 24,0 HRC and 25,2 HRC

From Formula (E.2), it follows  $\overline{H} = 24.6$  HRC and from Formula (E.3), it follows r = 1.2 HRC Rockwell units

Whichever is greater.

From Table E.1, for the HRC scale, the permissible repeatability range at HRC 24,6 = 0.02 (100 - 24,6) = 1,51 HRC Rockwell units. This is greater than 0.8 HRC Rockwell units, therefore, the permissible repeatability range of the testing machine for this reference block is 1.51 HRC Rockwell units.

Since r = 1.2 HRC Rockwell units, the repeatability of the testing machine is acceptable.

#### EXAMPLE 2

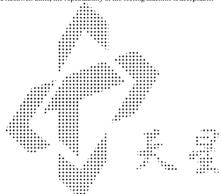

A high-hardness HRC block gave the following daily verification results:

63.1 HRC and 63.9 HRC

From Formula (E.2), it follows  $\overline{H} = 63.5$  HRC and from Formula (E.3), it follows r = 0.8 HRC Rockwell units.

From Table E.1, for the HRC scale, the permissible repeatability range at HRC 63.5 = 0.02 (100 - 63.5) = 0.73 HRC Rockwell units. This is less than 0.8 HRC Rockwell units, therefore, the permissible repeatability range of the testing machine for this reference block is 0.8 HRC Rockwell units.

Since r = 0.8 HRC Rockwell units, the repeatability of the testing machine is acceptable.

# Annex F (normative)

# Inspection of diamond indenters

Experience has shown that a number of initially satisfactory indenters can become defective after use for a comparatively short time. This is due to small cracks, pits, or other flaws in the surface. If such faults are detected in time, many indenters can be reclaimed by regrinding, if not, any small defects on the surface rapidly worsen and make the indenter useless. Therefore, the condition of indenters should be checked initially and at frequent intervals using appropriate optical devices (microscope, magnifying lass, etc.)

- the verification of the indenter is no longer valid when the indenter shows defects;
- Reground or otherwise repaired indenters shall be verified in accordance with the requirements of ISO 6508-2-2015

# Annex G

(informative)

# Uncertainty of the measured hardness values

#### G.1 General requirements

Measurement uncertainty analysis is a useful tool to help determine sources of error and to understand differences in test results. This Annex gives guidance on uncertainty estimation but the methods contained are for information only, unless specifically instructed otherwise by the customer. Most product specifications have tolerances that have been developed over the past years based mainly on the requirements of the product but also, in part, on the performance of the machine use to make the hardness measurement. These tolerances therefore incorporate a contribution due to the uncertainty of the hardness measurement and it would be interpretated by the stimated uncertainty of the hardness measurement. In other words, where a product specification states that the hardness of an item shall be higher or lower than item than the product specification states that the hardness of an item shall be higher or lower than item than the product specification states that the hardness of an item shall be higher or lower than item than the specification states that the hardness of an item shall be higher or lower than item than the product specification states that the product standard. However, the inhight be special productions where reducing the tolerance by the measurement uncertainty is appropriate. This shoultdook tandard was where reducing the tolerance by the measurement uncertainty is appropriate. This shoultdook tandard was where reducing the tolerance by the

Annex I shows the four level structure of the metrological chain necessary to define and disseminate hardness scales. The chain starts at the tloternational level using international definitions of the various hardness scales to carry but international intercomparisons. A number of primary hardness standard machines at the national level transfer of primary hardness reference blocks for the calibration laboratory level. Naturally, direct 124186245 on and the verification of these machines should be at the highest possible accuracy

#### G.2 General procedure

This procedure calculates an expanded uncertainty,  $U_i$  associated with the measured hardness value. Two different approaches to this calculation are given in Table,  $G_i$ , and Table,  $G_i$ , together with details of the symbols used. In both cases, a number of uncorrelated standard uncertainty sources are combined by the Root-Sum-Square (RSS) method and then multiplied by the coverage factor k = 2. In one approach, the uncertainty contribution from a systematic source is then added arithmetically to this value – in the other approach, a correction is made to the measurement resulting to compensating for this systemic component.

NOTE This uncertainty approach makes no allowance for any possible drift in the machine performance subsequent to its last calibration, as it assumes that any such changes will be insignificant in magnitude. As such, most of this analysis could be performed immediately after the machine's calibration and the results included in the machine's calibration certificate.

#### G.3 Bias of the machine

The bias, b, of a hardness testing machine (also termed 'error') is derived from the difference between

- the certified calibration value of the hardness reference block, and
- the mean hardness value of the five indentations made in the hardness reference block during calibration of the hardness testing machine.

and can be implemented in different ways into the determination of uncertainty.

#### G.4 Procedures for calculating uncertainty: Hardness measurement values

#### G.4.1 General

Two methods are given for determining the uncertainty of hardness measurements:

- Method M1: accounts for the systematic bias of the hardness machine in two different ways;
- Method M2: allows the detainable of uncertainty without having to consider the magnitude of the systematic bias.

Additional information on calculating hardness uncertainties can be found in the literature.[3][4]

NOTE In this Annex, the abbreviation "CRM" stands for "Certified Reference Material". In hardness testing standards, certified reference material seguivablent to the berings reference block, i.e. a piece of material with a certified value and associated upper parings:

#### G.4.2 Procedure with bias (method M1)

The method M1 procedure for the determination of measurement uncertainty is explained in Table G.1.

The measurement bias, b, of the hardness testing machine can be expected to be a systematic effect. In ISO/IEC Guith 98:352 it is reproposed that a correction be used to compensate for systematic effects, and this is the base of the correction be used to compensate for systematic effects, and this is the base of the correction of using this method is either all determined hardness values have to be reduced by b order uncertainty  $U_{corr}$  is as to be increased by b. The procedure for the determination of  $U_{corr}$  is explained in Table G.1.[4][2]

The combined expanded measurement uncertainty for a single hardness measurement is calculated as:

$$U = k \times \sqrt{u_{\rm H}^2 + u_{\rm ms}^2 + u_{\rm HTM}^2} \tag{G1}$$

where

- u<sub>H</sub> is a contribution to the measurement uncertainty due to the lack of measurement repeata solity of the hardness testing machine;
- $u_{
  m ms}$  is a contribution to the measurement uncertainty due to the resolution of the hardness testing machine;
- u<sub>HTM</sub> is a contribution to the measurement uncertainty due to the standard uncertainty of the bias, b, measurement generated by the hardness testing machine (this value is reported as a result of the indirect verification defined in ISO 6508-2:2015 and is defined according to Formula (6.2):

where

 $u_{\text{CRM}}$  is the contribution to the measurement uncertainty due to the calibration uncertainty of the certified value of the CRM according to the calibration certificate for k = 1;

uHCRM is the contribution to the measurement uncertainty due to the combination of the lack of measurement repeatability of the hardness testing machine and the hardness non-uniformity of the CRM, calculated as the standard deviation of the mean of the hardness measurements when measuring the CRM;

 $u_{
m ms}$  is the contribution to the measurement uncertainty due to the resolution of the hardness testing machine when measuring the CRM.

The result of the measurement is given by Formula (G.3) and Formula (G.4), respectively:

$$X_{\text{corr}} = (x - b) \pm U_{\text{corr}} \tag{G.3}$$

or by

$$X_{\text{ucorr}} = x \pm \left(U_{\text{corr}} + |b|\right) \tag{G.4}$$

depending on whether the bias (error), b, is considered to be part of the mean value or of the uncertainty.

When method M1 is used, it is a series appropriate to include additional uncertainty contributions within the RSS term relating to the table of the employed. This will particularly be the case when

- the measured hardness is significably different framithe hardness levels of the blocks used during the machine's cappration,
- the machine's bias value varies significantly throughout its calibrated range;
- the material being increased is different from the material of the hardness reference blocks used during the machine's calibration or
- the day-to-day performance (reproducibility) of the hardness testing machine varies significantly.

The calculations of these additional **contributions** to the measurement uncertainty are not discussed here. In all circumstances, a robust method for estimating the uncertainty associated with b is required.

#### G.4.3 Procedure without bias (method M2)

As an alternative to method M1, method M2 can be used in some circumstances. Method M2 is a simplified method which can be used without needing to consider the magnitude of any systematic error of the hardness testing machine; however, Method M2 usually over-estimates the real measurement uncertainty.

The procedure for the determination of U is explained in <u>Table G.2</u>.

Method M2 is only valid for hardness testing machines that have passed an indirect verification in accordance with ISO 6508-2:2015 using the value  $\Delta H_{HTMmax} = |b| + U_{HTM}$ , rather than only the bias value, b, when determining compliance with the maximum permissible deviation of the bias (see ISO 6508-2:2015).

In method M2, the bias (error) limit (the positive amount by which the machine's reading is allowed to differ from the reference block's value, as specified in ISO 6508-2:2015 is used to define one component  $b_F$  of the uncertainty. There is no correction of the hardness values with respect to the bias limit.

The combined expanded measurement uncertainty for a single future hardness measurement is calculated as:

$$U = k \times \sqrt{u_{\rm H}^2 + u_{\rm ms}^2} + b_{\rm E} \tag{G.5}$$

where

 $u_{\rm H}$  is a contribution to the measurement uncertainty due to the lack of measurement repeatability of the hardness testing machine;

u<sub>ms</sub> is a contribution to the measurement uncertainty due to the resolution of the hardness testing machine:

 $b_{\rm E}$  is the maximum permissible deviation of the bias as specified in ISO 6508-2:2015, and the result of the measurement is given by

$$X = x \pm U . (G.6)$$

## G.5 Expression of the gosult of measurement

When reporting the measurement result, the method (M1 or M2) used to estimate the uncertainty should also be specified.

EXAMPLE A hardness testing machine makes a single Rock well C hardness measurement, x, on a test sample.

Single hardness pressure pierit value, 
$$x$$
:  $x = 60.5$  HRC

Resolution of the hardness testing machine;  $\delta_{ms}$ :  $\delta_{ms}$  = 0.1 HRC

The last indiffer werification of the testing indchine determined a measurement bias, b, with an uncertainty of the has  $U_{\rm HTM}$  at  $U_{\rm HTM}$  and  $U_{\rm RTM}$  are  $U_{\rm HTM}$  and  $U_{\rm HTM}$  are the closest to the test sample inviginess of those CRMs used for the indirect verification.

Testing machine measurement bees 
$$b$$
:  $b$  =  $-0.72$  HRC Uncertainty of the testing machine measurement bias  $\psi_{\rm HTM}$ :  $\psi_{\rm HTM}$  = 0.66 HRC

To determine the lack of repeatability of the testing machine, the laboratory made five HRC measurements  $H_0$  on a CRM having a similar haddess to the test sample. The five measurements were made adjacent each other adhering to spacing requirements in order to reduce the influence of block non-uniformity.

Mean measurement value,  $\overline{H}$ :  $\overline{H} = 61,69 \text{ HRC}$ 

Standard deviation of the measurement values,  $s_H$ :  $s_H = 0.17$  HRC

where

$$\overline{H} = \frac{\sum_{i=1}^{n} H_i}{n} \tag{G.7}$$

and

$$s_{H} = \sqrt{\frac{1}{n-1} \sum_{i=1}^{n} (H_{i} - \overline{H})^{2}}$$
(G.8)

where n = 5.

The value of  $s_{\rm H}$  based on measurements from the last indirect verification according to ISO 6508-2:2015 may be used instead of conducting the above repeatability tests; however, this standard deviation value will usually overestimate the lack of repeatability uncertainty component since it also includes the CRM non-uniformity.

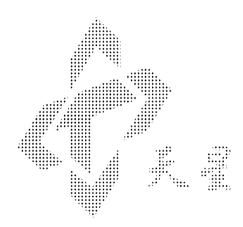

Table G.1 — Determination of the measurement result according to method M1

Step	Sources of uncertainty	Symbols	Formula	Literature/Certificate	Example [] = HRC

# Annex H (informative)

# **CCM - Working Group on Hardness**

In 1999, at the 88th Session of the International Committee of Weights and Measures (CIPM), Dr Kozo lizuka, President of the Consultative Committee for Mass and Related Quantities (CCM), state "Although the definition of hardness case is certainly conventional in the sense of the use of arbitrarily chosen formula, the testing method is defined by a combination of physical quantities expressed by SI units; the standard of hardness is established and maintained in most of MMIs and the traceability to the standard of NMIs is demanded in industry and elsewhere." The subsequent discussions led to the realization that hardness standards should be included in the key comparison database (KCDB) for the Mutual Recognition Arrangement (MRA), and thus, a full Working Group on Hardness (CCM-WGH) was established in the framework of the CCM-WGH).

The establishment of the CCM-WGH description of the first property of the CCM-WGH are not received as the proposed and approxed for NMI use to reduce the measurement differences at the highest national level. Due to the negocity of international agreement, the CCM-WGH has a close liaison with SO/TC 164/SC 3 in order to group rope, disagraphy that of the hardness cales. The most significant improvement of the CCM-WGH definitions with a CCM-WGH are a defined with specific values, rather than ranges and the composition of the CCM-WGH definitions with the composition of the CCM-WGH definitions as the values to use.

# Annex I

(informative)

# Rockwell Hardness Measurement Traceability

#### I.1 Traceability definition

The path to traceability for a Rockwell hardness measurement is different compared to many other measurement quantities, such as length or temperature. This is primarily because hardness measurement, including Rockwell, is made following a defined test procedure using a testing machine that makes multiple measurements of different parameters (e.g. force, depth, time) during the test. Each of these measurements, as well as other test parameters, influences the hardness result.

The International Vocabulary of Metrokay [XIM3][10] defines metrological traceability as the property of a measurement result whereby the result can be related to a reference through a documented unbroken chain of calibrations, each contributing to the measurement uncertainty.

From this definition, two things are necessary for a measurement result to have traceability:

- an unbroken chain of calibrations, each contributing lothe measurement uncertainty;
- b) a reference to which traceability is claimed.

These will define the metrological traceability chain.

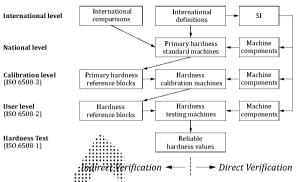

1.2 Chains of calibrations:::

ISO 6508-2:2015 specifies a set of call bration and verification procedures required to demonstrate that the testing machine is spitable for use in accordance with this part of ISO 6508. The calibration procedures include direct measuromers of various components affecting the machine's performance, such as the test forces, indenter shape, and depth measuring equipment, as well as hardness measurements of a range of reference blocks. Each of these calibration in easurements has specified limits within which the result should lie in order for the machine to pass its verification. Historically, the calibration and verification of the machine components has treen into the machine's Direct Verification and the calibration and verification of the testing machine by reference block measurements is *Indirect Verification*.

ISO 6508-3:2015 specifies both the procedure required to calibrate the reference blocks used in the Indirect Verification of the testing machine and also the required calibration and verification procedures of the machine used to calibrate these blocks.

When considering an "unbroken chain of calibrations" to provide measurement traceability to the testing machine, it is apparent that this could come via either the Direct Verification or Indirect Verification path.

Direct Verification requirements specify measurements of individual components of the testing machine. with traceability of each of these measurements being achieved through calibration chains to the International System of units (SI), usually as realized by a National Metrology Institute (NMI). These calibration chains are illustrated on the right-hand side of Figure I.1. Together, these calibration chains form a traceability path for a testing machine.

NOTE The left-hand side of Figure L1 illustrates a trageability path made through a single calibration chain or each level in the calibration thierarchy (i.e. National Stationard) and User) that includes the calibration for reference blocks and the subsequent \(\nu\)\

#### I.4 Practical issues

Either one of the two traceability paths of calibration chains illustrated in Figure L1 (left-hand side and right-hand side) could theoretically provide traceability to an appropriate Rockwell hardness reference. However, there are practical issues with both that should be considered. For the Direct Verification path given on the right-hand side of Figure L1, it is extremely difficult to identify, measure, and, if necessary, correct for all parameters that might affect the measured hardness value. Even if the machine passes its Direct Verification, traceability will not be ensured if one or more uncontrolled or unidentified parameters have a significant effect. This is often the case and becomes more of an issue at lower levels in the calibration hierarchy.

The Indirect Verification calibration chain shown on the left-hand side of Figure 1.1 also has practical issues to be considered. One consequence of using a testing machine having multiple components, each making measurements during the hardness test, is that an error in one component's measurement can be compensated or offset by an error in a different component's measurement. This can result in accurate hardness measurements for the specific hardness levels and block materials tested during the indirect verification; however, measurement error can increase when testing other hardness levels or materials. If the errors in the individual machine components are significant, then traceability may not be ensured again.

#### I.5 Rockwell hardness measurement traceability

#### IS1 General

The above issues indicate that both types of traceability path usually need to be in place for achieving Rockwell hardness measurement traceability. This does not mean that traceability cannot be achieved based on only one of the two paths, if careful examination and evaluation of the measurement process is made. For example, at the National 124vel, the traceability of an NMI's primary Rockwell hardness standard machine is achieved through 3 direct perification calibration chain since there is no recognized higher-level hardness reference artestat. That ability through this path is possible since NMIs typically have the capability to thoroughly 3041vid 124vir measurement systems, and their uncertainty levels are confirmed through internationic companisms with other NMIs. In contrast, decades of Rockwell hardness measurement experience has shown that, for the lower levels in the calibration hierarchy, it is most practical to obtain traceability and determine measurement uncertainty based primarily on the Indirect Verification calibration chair; howerth proper in the calibration before component quantity values is also important. TRES 11342401818 \$204146 has proven to be suitable for industrial Rockwell hardness measurements:

## 1.5.2 Calibration fevel traccentifity

Measurement tracebody is best being a librated at the National level (NMI). This is also the path that should be usely by the deep majorition of measurement pricertainty. At the second in the path that should be usely by the determination of measurement pricertainty. At the same time, however, the specified components in the calibration maddine should be calibrated on a frequent basis to ensure that offsetting errors are not significant. We disease traceability should be in the NMI's realization of the CCM-WCH definition of the Rockwell scale or, when there is an absence of a CCM-WCH definition; traceability should be to the NMI's idalization of its own those idefinition. If the NMI does not provide calibrated reference blocks or correct some insurance with a Calibration laboratory and it is not practical to use reference thocks of another NMI, then the reference to which traceability is claimed might need to be to the Calibration laboratory's realization of the Rockwell scale definition based on an international test method, such as that defined by the ISO 6508- series. In this case, the Calibration laboratory's measurement traceability can be achieved through the Indirect Verification path using consensus reference block standards, or through the Direct Verification path confirmed by intercomparisons.

#### I.5.3 User level traceability

Measurement traceability is best obtained through the Indirect Verification calibration chain using reference blocks that have been calibrated at the Calibration level or National level. As with Calibration level traceability, this is the most practical path and should also be used for the determination of measurement uncertainty. It is also desirable that the components of the hardness machine periodically undergo Direct Verification to ensure that offsetting errors are not significant. However, typical industrial practice is for these measurements to be made only when the hardness machine is manufactured or repaired, which is the minimum requirement of the ISO 6508- series.

NOTE The following terms used in this Annex are in accordance with the VIM3[19]: calibration, calibration hierarchy, metrological traceability, metrological traceability chain, ordinal quantity and verification.
